Understanding Blade Element Momentum (BEM) Theory

What is BEM Theory?

Blade Element Momentum (BEM) theory is a semi-empirical method used to predict the aerodynamic performance of wind turbine blades or helicopter rotors. It combines two main approaches:

- Blade Element Theory: Divides the blade into small elements along its length and calculates local forces based on airfoil characteristics.
- Momentum Theory: Applies conservation of momentum to estimate the axial and tangential forces on the rotor based on the flow through the rotor disk.

By integrating these approaches, BEM provides a detailed force distribution along the blade span and predicts performance parameters such as torque, power, and thrust.

Key Assumptions in BEM

- The flow is steady and incompressible.
- The blade elements are small enough that flow conditions are uniform across each element.
- Induction factors (axial and tangential) are uniform across the rotor disk.

- Tip and root losses are often included via correction factors.
- The blade is assumed to be rigid and fixed in the rotor hub.

Matlab Implementation of BEM Theory

Creating a MATLAB code for BEM involves several key steps:

- Defining the rotor geometry and blade parameters.
- Calculating local flow angles and velocities.
- Applying blade element theory to compute forces.
- Using momentum theory to determine induction factors.
- Iterating to achieve convergence.
- Summing forces to find overall performance metrics.

Below, we delve into each step, providing code snippets and explanations.

1. Defining Rotor and Blade Parameters

Begin by specifying rotor parameters such as rotor radius, number of blades, blade pitch angle, air density, and blade geometry.

```matlab

% Rotor parameters

R = 50; % Rotor radius in meters

B = 3; % Number of blades

rho = 1.225; % Air density in kg/m^3

omega = 2; % Rotational speed in rad/sec

n_sections = 20; % Number of blade elements

% Blade geometry

r = linspace(3, R, n_sections); % Radial positions from hub to tip

chord = 3 ones(1, n_sections); % Uniform chord length (meters)
```

twist = linspace(10, 0, n_sections); % Twist angle from root to tip in degrees

% Airfoil data (lift and drag coefficients)

% For simplicity, use linear approximations or data tables

% Here, assume constant CL and CD for demonstration

CL_alpha = 2 pi; % Lift curve slope

CD0 = 0.01; % Zero-lift drag coefficient

```

## 2. Calculating Local Flow Velocities

At each blade element, compute the relative wind velocity considering the axial and tangential components, as well as the induction factors.

```matlab

% Initialize induction factors

a = zeros(1, n_sections); % Axial induction factor

a_prime = zeros(1, n_sections); % Tangential induction factor

% Initial guess for induction factors

a(:) = 0.3;

a_prime(:) = 0.01;

% Loop over blade elements for iterative solution

max_iter = 100;

tolerance = 1e-4;

for iter = 1:max_iter

for i = 1:n_sections

% Local velocities

V_axial = 0; % Free stream axial velocity (assumed zero for hover or known wind speed)

V_rel = sqrt((omega r(i) (1 + a_prime(i)))^2 + (V_axial (1 - a(i)))^2);

phi = atan2(V_axial (1 - a(i)), omega r(i) (1 + a_prime(i))); % inflow angle in radians

% Convert to degrees for twist and angle calculations

alpha = phi (180 / pi) - twist(i); % Angle of attack

% Aerodynamic coefficients

CL = CL_alpha (alpha pi/180); % Linear approximation

CD = CD0; % Constant drag coefficient

% Calculating lift and drag forces

L = 0.5 rho V_rel^2 chord(i) CL;

D = 0.5 rho V_rel^2 chord(i) CD;

% Resolve forces into axial and tangential components

% Using inflow angle phi

F_L = L;

F_D = D;

% Force components

F_axial = F_L cos(phi) + F_D sin(phi);

F_tangential = F_L sin(phi) - F_D cos(phi);

% Update induction factors using momentum theory

```
a_new = 1/3; % Placeholder, will be updated

a_prime_new = 1/3; % Placeholder, will be updated

% (Implement equations for a and a_prime here)

% For simplicity, here we set placeholder values

a(i) = a_new;

a_prime(i) = a_prime_new;

end

% Check for convergence

if max(abs(a - a))
break;

end

end
```

Note: The above code provides a conceptual framework. In practice, you would implement the iterative equations derived from BEM theory to update `a(i)` and `a_prime(i)` until convergence.

3. Computing Forces and Power Output

Once the induction factors converge, calculate the differential forces and integrate along the blade to find total torque and power.

```matlab
% Initialize total torque and thrust

total_torque = 0;

total_thrust = 0;
```

```
for i = 1:n_sections

phi = atan2(V_axial (1 - a(i)), omega r(i) (1 + a_prime(i)));

V_rel = sqrt((omega r(i) (1 + a_prime(i)))^2 + (V_axial (1 - a(i)))^2);

CL = CL_alpha (phi (180 / pi) - twist(i));

CD = CD0;

L = 0.5 rho V_rel^2 chord(i) CL;

D = 0.5 rho V_rel^2 chord(i) CD;

F_L = L;

F_D = D;

% Force components

F_axial = F_L cos(phi) + F_D sin(phi);

F_tangential = F_L sin(phi) - F_D cos(phi);

% Differential torque and thrust

dT = B r(i) F_tangential;

dQ = B r(i) F_tangential r(i);

total_thrust = total_thrust + F_axial dr(i);

total_torque = total_torque + dQ;

end

% Power calculation

power = omega total_torque;

fprintf('Total Power Output: %.2f Watts\n', power);
```

```

Note: Proper numerical integration over the blade span requires defining `dr` (differential element length) and summing contributions accurately.

element theory with momentum theory to predict the aerodynamic performance of rotating blades efficiently. For engineers and researchers working in renewable energy and aerodynamics, implementing BEM theory in Matlab provides a flexible and powerful tool for simulation, optimization, and understanding of rotor behavior.

In this article, we'll delve into the Matlab code for Blade Element Momentum theory, exploring its fundamentals, step-by-step implementation, and practical considerations. Whether you're a student learning about rotor aerodynamics or a professional developing a turbine model, this guide aims to provide a detailed understanding to help you develop or refine your Matlab scripts.

Understanding Blade Element Momentum Theory

Before jumping into the code, it's crucial to grasp the core concepts behind BEM theory.

What is Blade Element Theory?

Blade Element Theory (BET) simplifies the aerodynamic analysis of a rotor blade by dividing it into small segments or elements along its span. Each element is treated as an independent airfoil, and the forces are calculated based on local flow conditions, blade geometry, and airfoil data (lift and drag coefficients).

What is Momentum Theory?

Momentum Theory provides a global perspective by considering the conservation of momentum in the flow through the rotor disk. It relates the change in axial and tangential momentum flux to the forces exerted by the rotor, enabling the calculation of induced velocities and power.

Combining BET and Momentum Theory

Blade Element Momentum (BEM) theory merges BET and momentum theory by iteratively solving for the flow conditions at each blade element. It accounts for the local aerodynamic forces and the induced velocities caused by the rotor's thrust, leading to a comprehensive performance prediction.

Step-by-Step Implementation of BEM Theory in Matlab

Implementing BEM theory involves several steps, including defining blade geometry, airfoil data, initializing flow conditions, iteratively solving for induction factors, and calculating performance metrics. Let's break down these steps.

- Define Blade Geometry and Rotor Parameters

Set parameters such as:

- Rotor radius `R`
- Blade chord distribution `c(r)`
- Blade twist distribution `?(r)`
- Number of blades `B`
- Number of blade elements `N`
- Tip speed ratio `?`
- Rotational speed `?`

These parameters define the physical and operational characteristics of the rotor.

- Import or Generate Airfoil Data

Airfoil data provides lift `Cl` and drag `Cd` coefficients as functions of angle of attack `?`. This data can be:

- Imported from experimental measurements
- Generated via airfoil analysis tools
- Assumed via empirical models

For simplicity, a lookup table or polynomial fit can be used within Matlab.

- Discretize the Blade into Elements

Divide the blade span into `N` segments:

```matlab

r = linspace(r_root, R, N); % radial positions

dr = (R - r_root)/N; % differential span length

```

Compute local geometric parameters at each element.

- Initialize Induction Factors

Induction factors determine the flow modification caused by the rotor:

- Axial induction factor `a`
- Tangential induction factor `a'`

Start with initial guesses, typically:

```matlab

a = 0.3; % initial axial induction factor

a_prime = 0; % initial tangential induction factor

```

- Iterative Solution Loop

For each blade element, perform the following:

a. Calculate Local Flow Velocities

- Axial velocity at the rotor: `V_axial = V_inf (1 - a)`
- Tangential velocity: `V_tangential = ? r (1 + a')`

b. Determine Relative Wind Speed and Inflow Angle

```matlab

V_rel = sqrt( (V_axial)^2 + (V_tangential)^2 );

? = atan2(V_axial, V_tangential); % inflow angle in radians

```

c. Calculate Angle of Attack

```matlab
? = rad2deg(?) - blade_twist(r); % degree
```

d. Interpolate Airfoil Data

Using `?`, interpolate `Cl` and `Cd` from airfoil data.

e. Compute Aerodynamic Forces

```matlab
L = 0.5 rho V_rel^2 c(r); % lift force per unit span
D = 0.5 rho V_rel^2 c(r); % drag force per unit span
```

Break forces into axial and tangential components:

```matlab
dT = L cos(?) + D sin(?); % differential thrust
dQ = (L sin(?) - D cos(?)) r; % differential torque
```

f. Update Induction Factors

Using momentum theory:

```matlab
% Axial induction
a_new = 1 / (1 + (4 sin(?)^2) / (? Cl));
% Tangential induction
```

a_prime_new = 1 / ((4 sin(?) cos(?)) / (? Cl) - 1);

```

Iterate until convergence:

```matlab

while abs(a_new - a) > tol || abs(a_prime_new - a_prime) > tol

a = a_new;

a_prime = a_prime_new;

% Recompute velocities, inflow angle, ?, forces

% Recalculate a_new and a_prime_new

end

```

- Calculate Power and Thrust

After convergence:

```matlab

Thrust = sum(dT dr);

Power = sum(dQ ?);

```

Compute the power coefficient `Cp` and thrust coefficient `Ct` relative to rotor swept area and wind power.

Practical Considerations and Enhancements

Implementing BEM in Matlab can be straightforward, but real-world applications demand attention to
```

several factors:

- Airfoil Data Accuracy: Use high-quality CL and CD data across the relevant ? range.
- Tip Loss Corrections: Incorporate corrections like Prandtl?s tip loss factor to account for finite blade effects.
- Hub Losses: Consider hub effects to improve accuracy.
- Dynamic Stall and Wake Effects: For transient or complex flows, extend the model to include unsteady effects.
- Optimization: Use the Matlab Optimization Toolbox to optimize blade twist and chord distributions for maximum efficiency.

Sample Matlab Code Snippet

Here's a simplified snippet illustrating core BEM calculations:

```matlab

% Define parameters

R = 50; % rotor radius in meters

B = 3; % number of blades

rho = 1.225; % air density

V_inf = 10; % free stream wind speed

Omega = 2 pi 10 / 60; % rotational speed in rad/sec

N = 20; % number of blade elements

% Discretize blade

r = linspace(0.2R, R, N);

c = 3; % constant chord for simplicity

theta = deg2rad(20); % constant twist

% Initialize variables
```

```
a = zeros(1, N);

a_prime = zeros(1, N);

for i = 1:N

for iter = 1:100

V_axial = V_inf (1 - a(i));

V_tangential = Omega r(i) (1 + a_prime(i));

V_rel = sqrt(V_axial^2 + V_tangential^2);

phi = atan2(V_axial, V_tangential);

alpha_deg = rad2deg(phi) - rad2deg(theta);

% Lookup Cl, Cd based on alpha_deg

[Cl, Cd] = airfoilCoefficients(alpha_deg);

sigma = (B c) / (2 pi r(i));

a_new = 1 / (1 + (4 sin(phi)^2) / (sigma Cl));

a_prime_new = 1 / ((4 sin(phi) cos(phi)) / (sigma Cl) - 1);

% Check convergence

if abs(a_new - a(i))
break;

end

a(i) = a_new;

a_prime(i) = a_prime_new;

end
```

```
% Calculate forces

L = 0.5 rho V_rel^2 c;

D = 0.5 rho V_rel^2 c;

dT = (L cos(phi) + D sin(phi)) dr;

dQ = (L sin(phi) - D cos(phi)) r(i) dr;

% Accumulate total thrust and torque

end
```

This snippet demonstrates the core iterative process but should be expanded with actual airfoil data, tip loss corrections, and performance calculations for a complete model.
