Understanding Signals and Systems

What Are Signals?

Signals are functions that convey information about the behavior or attributes of a phenomenon. They can be classified based on various criteria:

- Continuous-Time vs Discrete-Time Signals

Continuous-time signals are defined for every instant in time (e.g., analog audio signals), while discrete-time signals are defined only at discrete moments (e.g., digital recordings).

- Analog vs Digital Signals

Analog signals are continuous in both time and amplitude, whereas digital signals are discrete in both respects, usually represented by binary values.

- Periodic vs Aperiodic Signals

Periodic signals repeat at regular intervals, such as sine waves, while aperiodic signals do not.

- Energy vs Power Signals

Energy signals have finite energy but zero average power; power signals have finite, non-zero average power.

Types of Systems

A system can be viewed as a device or process that takes an input signal and produces an output signal. Systems are characterized based on their properties:

- Linearity

A system is linear if it satisfies superposition and homogeneity.

- Time-Invariance

A system is time-invariant if its behavior does not change over time.

- Causality

A causal system's output depends only on present and past inputs.

- Stability

A system is stable if bounded inputs produce bounded outputs.

Understanding these properties helps in designing and analyzing systems efficiently and predicting their behavior.

Mathematical Foundations of Signals and Systems

Signal Representation

Signals are often represented mathematically as functions, such as:

- $x(t)$ for continuous-time signals
- $x[n]$ for discrete-time signals

These functions can be analyzed using various transforms to simplify operations like convolution, filtering, and stability analysis.

System Representation

Systems are typically modeled using differential equations (for continuous-time) or difference equations (for discrete-time). For example:

- Continuous-time systems: $\frac{dy(t)}{dt} + ay(t) = bx(t)$
- Discrete-time systems: $y[n] - ay[n-1] = bx[n]$

Transform methods are employed to convert these equations into algebraic forms, making solutions more straightforward.
