Sample Data Structures Lab Viva Questions with Answers

Providing students with sample questions and model answers can greatly aid preparation.

Q1. What is a linked list? Explain its types.

Answer:

A linked list is a linear data structure where elements, called nodes, are linked using pointers. Each node contains data and a reference (pointer) to the next node in the sequence. Types include:

- Singly Linked List: Each node points to the next node.
- Doubly Linked List: Each node points to both the next and previous nodes.
- Circular Linked List: The last node points back to the first node, forming a circle.

Q2. Write a program to implement a stack using arrays.

Answer:

```
```python
```

```
class Stack:
```

```
def __init__(self, size):
```

```
 self.stack = [None] * size
```

```
 self.top = -1
```

```
 self.size = size
```

```
def push(self, item):
```

```
 if self.top == self.size - 1:
```

```
 print("Stack Overflow")
```

```
 else:
```

```
self.top += 1

self.stack[self.top] = item

def pop(self):

if self.top == -1:

print("Stack Underflow")

else:

item = self.stack[self.top]

self.top -= 1

return item

def display(self):

if self.top == -1:

print("Stack is empty")

else:

for i in range(self.top, -1, -1):

print(self.stack[i])

...
```

### **Q3. How do you detect a cycle in a directed graph?**

Answer:

Cycle detection in a directed graph can be performed using Depth-First Search (DFS). Maintain two arrays: one to keep track of visited nodes and another to keep track of nodes in the current DFS recursion stack. If during DFS, a node is encountered that is already in the recursion stack, a cycle exists.

### Algorithm Steps:

- Mark the current node as visited and add it to the recursion stack.
- Recursively visit all adjacent nodes.
- If an adjacent node is already in the recursion stack, a cycle is detected.
- Remove the current node from the recursion stack after exploring all adjacent nodes.

**Question** What are data structures and why are they important in programming? Data structures are specialized formats for organizing, storing, and managing data efficiently. They are important because they enable efficient data retrieval, modification, and storage, which improves the performance and scalability of algorithms and programs. Explain the difference between an array and a linked list. An array is a collection of elements stored in contiguous memory locations, allowing fast access via indices. A linked list consists of nodes where each node contains data and a reference to the next node, enabling dynamic memory allocation but with slower access times compared to arrays. What is a stack, and how is it different from a queue? A stack is a data structure that follows the Last In First Out (LIFO) principle, where the last added element is removed first. A queue follows the First In First Out (FIFO) principle, where the first added element is removed first. Describe the concept of a binary search tree (BST). A binary search tree is a binary tree where each node has at most two children, with the left child containing values less than the parent node and the right child containing values greater than the parent. It allows efficient search, insertion, and deletion operations. What are hash tables, and how do they work? Hash tables are data structures that store key-value pairs and use a hash function to compute an index for each key, enabling fast data retrieval. Collisions are handled using methods like chaining or open addressing. Explain the concept of recursion in data structures with an example. Recursion is a technique where a function calls itself to solve a problem by breaking it into smaller subproblems. For example, calculating factorial of a number  $n$  uses recursion:  $\text{factorial}(n) = n \times \text{factorial}(n-1)$ , with base case  $\text{factorial}(0) = 1$ .
